Dynamics based Maintenance T.Tinga@utwente.nl utwente.nl/time

Predictive Maintenance Promises & practical challenges

WCM jaarevent 'samen slimmer'

Prof. dr. ir. Tiedo Tinga Life Cycle Management T.Tinga@mindef.nl

Outline

Introduction

- Predictive Maintenance
 - Approaches
 - The promise
- Challenges in (application of) PdM
- Solutions

Introduction

Industry & governments

- Increasing demands for availability and reliability of critical assets
- Abundant (sensor) data → Industry 4.0

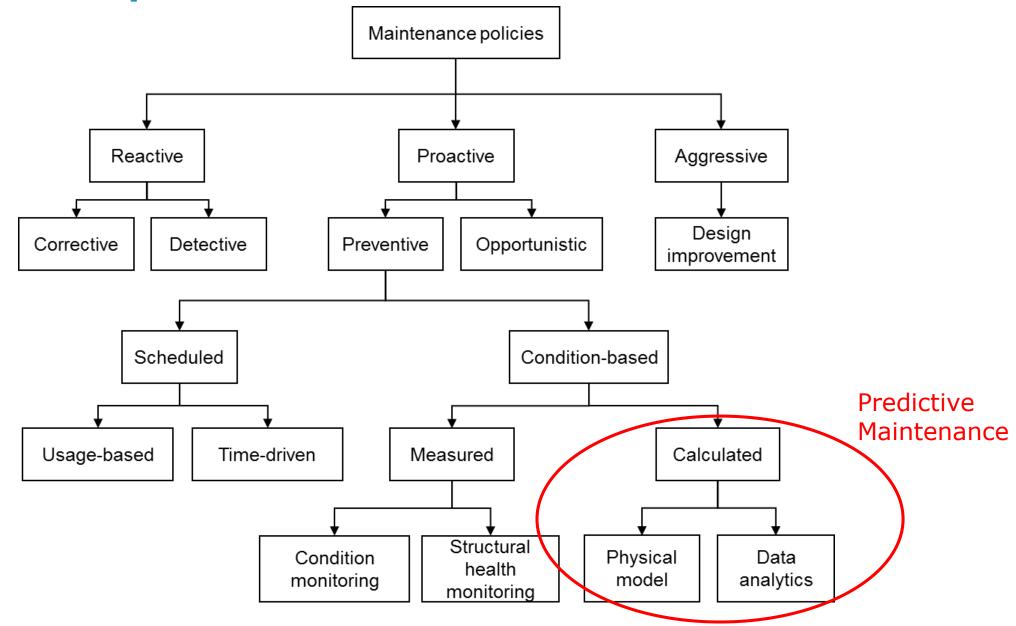

Potential & demand for data-driven maintenance

- Diagnostics → Condition based Maintenance (CBM)
- Prognostics → Predictive Maintenance (PdM)

- Despite available methods and scientific papers
 - → application of PdM in (industrial) practice limited

Maintenance policies

Prognostics – approaches

Experience-based (traditional)

- Experience from past / collected data
 - → often conservative
 - → not always available (registration, PM)
 - → Not always representative

Data-driven

- Derive relations from big data sets (e.g. sensors)
- Use AI / Machine Learning
 - → Sometimes unexpected relations, but is *black box*
 - → not always representative

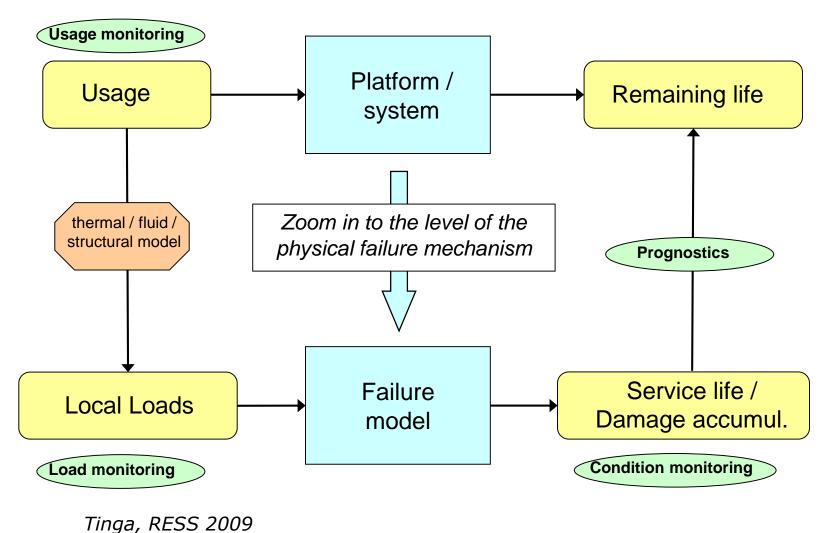

Model-based

- Model of physical failure mechanism
- Input from monitored usage / loads
 - → Always representative, takes large effort

Model-based: relation usage – life time

The promise of Predictive Maintenance...

- All failures can (and will) be prevented
- 100% predictability of failures
- Data is abundant, everything is connected
- AI will solve everything

8

Why limited application of PdM?

- Ambitioned Maturity Level vs Data Requirements
 - 1. Detection: is something wrong?
 - Anomaly Detection
 - only requires unlabeled (sensor) data
 - 2. Diagnosis: what is wrong?
 - Classification
 - requires labeled data (supervised learning) for all faults
 - 3. Health assessment: how wrong is it?
 - Condition monitoring
 - requires dedicated CM sensors & threshold value
 - 4. Prognosis: when is it expected to go wrong?
 - Regression, Prediction
 - requires run-to-failure data & operational history

Two main barriers identified

1. Mismatch ambition level and available data + knowledge

Often unaware → frustrates developments

2. Lack of relevant data in industrial practice

- No labelling
 - > lack of failures & low quality registration
- No condition measurements
 - > not many CM sensors, indirect methods
- No threshold value
 - > especially for indirect CM, often trial-and-error
- No run to failure data
 - > failures prevented for critical systems (→ simulations, benchmark, CMAPSS)
- No operating history
 - > not registered, changing configurations

Solution directions

1. Accept

finding the most suitable approach given the (limited) data

2. Circumvent

combine limited data with physical models

3. Extend

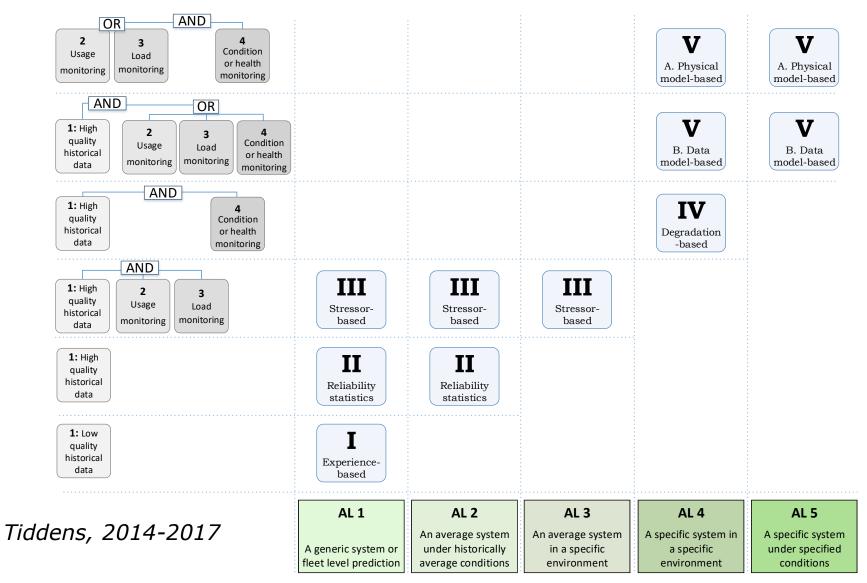

collect additional (relevant) data

Matching ambition and data

ACCEPT

Fitting PdM ambition to data

13 WCM jaar event 10/3/2025

PdM scoring method

Suitability

- match with ambition

Feasibility

match with data / knowledge

Expert system

Pre-filled with questions and scores per MT

Silveira, 2023

prediction (A1) for individual systems? (No for fleet average values). (A2) for generalized cases? (A3) for varying operational conditions? 14 WCM jaar event

Combine data & models

CIRCUMVENT

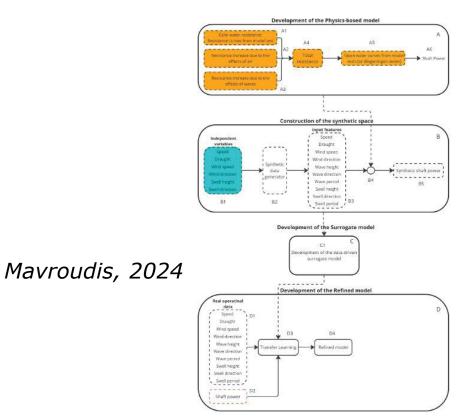

Complement data with models

- Data-driven approach often infeasible
 - limited failure data and lack of labelling
- Physics-of Failure models
 - contain relations for degradation
 - only need 'fitting parameters' → use data
 + Particle Filter

or Transfer Learning

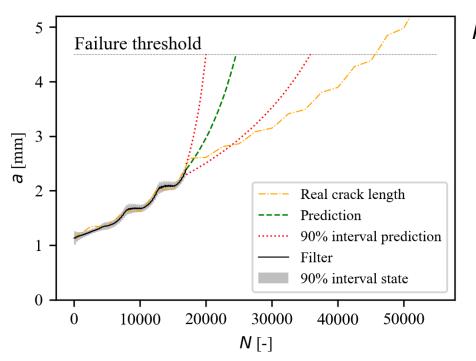

Keizers, 2024

WCM jaar event

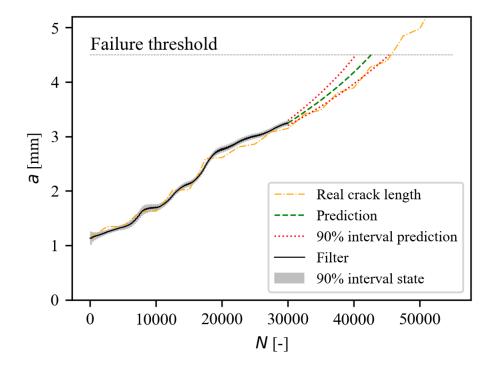

Hybrid approaches

Combine physics/monitoring

- Physics for (long term) prediction
- Data to keep model 'on track'

Keizers, 2021

Prediction before load change

Prediction after load change

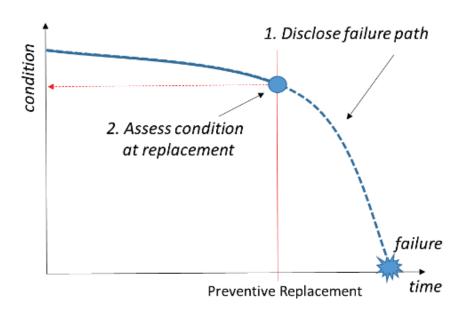

Collect additional data

EXTEND

Generation of labeled (failure) data

Missing info

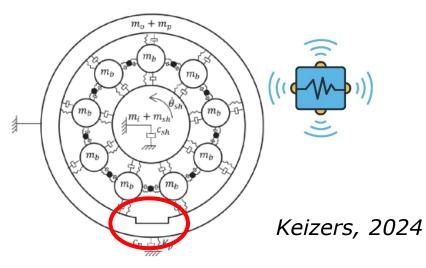

- Run-to-failure part
- Condition at replacement

Assess condition

- Experts register condition of replaced parts
- Use numerical models to translate indirect into direct CI

Generation of labeled failure data

Testing in laboratory setting

- accelerated testing + run-to-failure
- fully controlled → all potential faults
- completely labeled dataset (NLN-EMP)

Bruinsma, 2024

Test in field → Front runner

- Postpone PM for small fraction of systems
- Ensure to lead the fleet (age) + limit failure effects → failures!

Benefits

- Rest of fleet → PM closer to actual life time
- Additional (sensor) data reveals patterns related to failures

2. Assess condition at replacement

Preventive Replacement

1. Disclose failure path

Dutch Prognostics Lab

Public datasets (CMAPSS, CWRU, FEMTO-ST, ...)

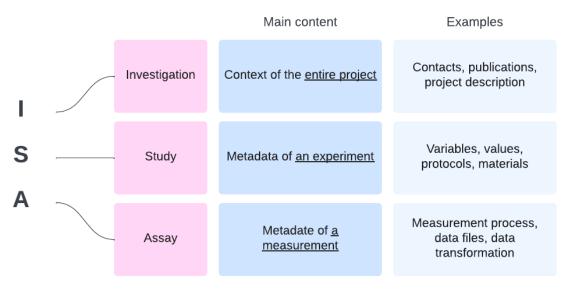

- Limited # sets, with large faults
- Format & labeling heterogeneous
- → Difficult to use for AI method development

Distributed testing

More labeled run-to-failure data - 6 (research) organizations in NL

Standardize labeling - ISA-PHM

- Metadata format (from biology)
 - > Diagnostic / prognostic
 - > Fault type(s)
 - > Operational conditions
- Upload test data in database
- Retrieve data for modeling
- See www.ISA-PHM.com

21 WCM jaar event 10/3/2025

Conclusion

- Predictive Maintenance has potential in increasing availability / reducing costs
- Ultimate ambition is 100% prediction of failures
- Both data science / AI and physics of failure play an important role

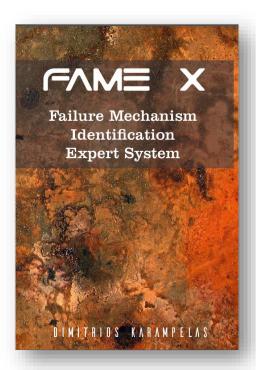

But:

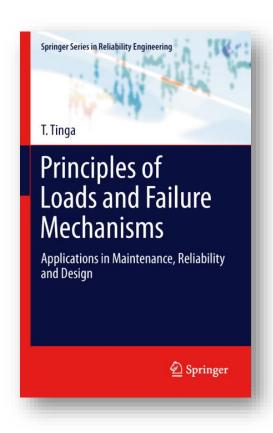

- Not the easiest application field for data science
- Challenges in transfer from theory to practice (data!)
- Hybrid approaches seem to be suitable to solve this
